Legislative Request

This report is issued to comply with [2014 Laws of Minnesota, Chapter 312, Article 11, Section 36](#).

Sec. 36. EVALUATION OF CERTAIN TRUNK HIGHWAY SPEED LIMITS.

Subdivision 1. Engineering and traffic investigations.

The commissioner of transportation shall perform engineering and traffic investigations on trunk highway segments that are two-lane, two-way roadways with a posted speed limit of 55 miles per hour. On determining upon the basis of the investigation that the 55 miles per hour speed limit can be reasonably and safely increased under the conditions found to exist on any of the trunk highway segments examined, the commissioner may designate an increased limit applicable to those segments and erect appropriate signs designating the speed limit. The new speed limit shall be effective when the signs are erected. Of all the roadways to be studied under this section, approximately one-fifth must be subject to investigation each year until the statewide study is complete in 2019.

Subd. 2. Report.

By January 15 annually, the commissioner shall provide to the chairs and ranking minority members of the senate and house of representatives committees with jurisdiction over transportation policy and finance a list of trunk highways or segments of trunk highways that were subject to an engineering and safety investigation in the previous calendar year, specifying in each case the applicable speed limits before and after the investigation.

EFFECTIVE DATE.

This section is effective the day following final enactment and expires on the earlier of Jan. 15, 2019, or the date the final report is submitted to the legislative committees under this section.

The cost of preparing this report for 2018 is \$220,782. The total cost of this reporting requirement over the 5-year period is \$1,179,402.

2018 Project Costs (12/1/2017 - 11/13/2018)	
MnDOT Staff Time	
Project Management, speed sampling, and data analysis	\$125,021
Consultant Costs	
Field Work	\$68,797
Project Management, speed sampling, and data analysis	\$26,964
2018 Total	\$220,782

2017 Project Costs (1/1/2017 - 11/15/2017)	
MnDOT Staff Time	
Project Management, speed sampling, and data analysis	\$93,757
Consultant Costs	
Field Work	\$70,680
Project Management, speed sampling, and data analysis	\$63,067
2017 Total	\$227,504

2016 Project Costs (1/1/2016 - 11/15/2016)	
MnDOT Staff Time	
Project Management, speed sampling, and data analysis	\$129,112
Consultant Costs	
Field Work	\$104,650
Project Management, speed sampling, and data analysis	\$19,816
2016 Total	\$253,578

2015 Project Costs (1/1/2015 - 11/25/2015)	
MnDOT Staff Time	
Project Management, speed sampling, and data analysis	\$158,703
Consultant Costs	
Field Work	\$75,110
Project Management, speed sampling, and data analysis	\$122,672
2015 Total	\$356,485

2014 Project Costs (1/1/2014 - 12/31/2014)	
MnDOT Staff Time	
Project Management, speed sampling, and data analysis	\$77,959
Consultant Costs	
Field Work	\$11,630
Project Management, speed sampling, and data analysis	\$31,464
2014 Total	\$121,053

Summary

Minnesota has approximately 7,000 miles of two-lane, two-way roadways that are affected by [2014 Laws of Minnesota, Chapter 312, Article 11, Section 36](#). As a result of the study required by this legislation, the speed limit was increased to 60 miles per hour on 5,240 miles (77 percent) of the two-lane state highway system. MnDOT previously increased speeds to 60 miles per hour on 1,550 mile of two-lane highways. When all of the speed limit signs are installed, 81 percent of the two-lane, two-way state highways will have a posted speed limit of 60 miles per hour.

Of the nearly 7,000 miles studied, about 5,000 of these miles crossed the borders of different Minnesota Department of Transportation districts and required coordination with the districts to conduct a speed study. A schedule of miles to be studied by year and district was developed for these 5,000 or so miles and is shown in Appendix C. The remaining 2,000 miles did not cross MnDOT district boundaries and the timeline for their study was left to the discretion of the district.

All Minnesota two-lane roadways with a current speed limit of 55 miles per hour were identified and then divided into two categories: coordinated routes and discretionary routes based on whether the roadway crossed a MnDOT district boundary. The coordinated routes were distributed over the 5-year study period, taking care to schedule the same highway in the same year across district borders.

Knowing that the 2014 study period would be shortened because of the timing of the law and the need to set expectations and procedures for a 5-year study, year one (2014) was assigned fewer miles than the remaining years in the study. Although the initial plan included studying more roadways within 2014, the short timeframe only allowed for the study of approximately 65 percent of the planned coordinated routes and 30 percent of the discretionary routes.

To date, 100 percent of all routes originally proposed for the 5-year project were studied and authorized – 100 percent of all coordinated routes are complete and 100 percent of all discretionary routes are complete. The winter and spring months will be used to install regulatory signs.

Post Study Analysis

In order to assess the impact of raising speed limits on travel speed, vehicle travel speeds were recorded before and after speed limits were increased. A random sample of locations throughout the state where speed limits were raised and where speed limits remained the same was the basis for comparing the results and providing statistically significant findings. These findings are based on 46 locations where the speed limit increased to 60 miles per hour and 22 locations where the speed limit remained at 55 mph. The results comparing the speeds before and after any speed limits changes, if implemented, for the 68 locations are shown in Table 1 below.

The table below shows multiple measures of roadway speed. The 85th percentile speed is a measure used by engineers to set roadway speeds. The 85th percentile speed is the speed at which 85 percent of drivers are traveling or below. The mean speed shows the average speed that drivers are traveling. The standard deviation gives context to how travel speeds are distributed. The standard deviation shows the number of miles per hour greater than and less than the mean or average. This measure shows the average of the highest five travel speeds and offers an understanding of extreme speeds.

Table 1: Before and After Data for Speed Limit Changes

	Before Speed Limit Change	After Speed Limit Change
85th Percentile Speed	65 mph	65 mph
Mean Speed	59 mph	60 mph
Standard Deviation	6.4 mph	6.1 mph
Average of Five Highest Speeds	76 mph	76 mph

Note: This analysis includes roadway speed data from the forty-six randomly selected locations where the posted speed limit was changed.

Using the 68 locations throughout the state, it was found that there was no change in the 85th percentile speed after the installation of the 60 mile per hour speed limit. The mean speed increased by one mile per hour and the standard deviation reduced slightly. After speed limits increased travel speeds at the locations sampled were slightly more consistent between each vehicle. In other words, more drivers traveled at a similar speed after speed limits increased. This is a desirable outcome, but this change is very slight and may not impact the frequency or severity of crashes.

Study Details

Study Overview

This study covers a widespread geographical area over a 5-year timeframe. The main tasks for the study include data collection, data analysis, writing recommendations for speed limits, drafting speed authorizations and signing roadways with the resulting speed limit.

To comply with the legislative language, a study schedule, included in Appendix C, was created for all two-lane, two-way roadways with a 55 mph speed limit in Minnesota.¹ Upcoming roadwork and personnel workload were considered when each roadway was scheduled. Roadways that do not cross MnDOT borders and remain solely in one MnDOT district were not included in the schedule. Instead, the district was allowed to decide when to conduct the study, as long as the roadway or segment was studied within the 5-year timeframe. Adjustments to this schedule were made when necessary due to construction activities on state or local roads within the study area, weather or other unforeseen conditions arose. There were fewer miles of roadway studied in 2014 than in subsequent years because of the limited time available since the effective date of the statute. All the required roadways and segments were analyzed during the 5-year timeframe.

Each of the required roadways had a speed study done. A speed study analyzes the speed at which 85 percent of drivers choose to drive on a road. The study recommended a speed limit appropriate to how the road was driven. Many other factors also influenced the recommendation, such as the number of access points, shoulder width and crash history. Nine factors were included on the speed study screening considerations worksheet. A sample of this worksheet is included in Appendix D. The nine factors are discussed in greater detail in the next section.

Once the speed study was completed, the MnDOT district traffic engineer reviewed all data collected and made the final recommendations for an appropriate speed limit. When a recommendation to increase a speed limit was made, the MnDOT Office of Traffic Engineering reviewed the new speed authorization. Recommended speed limit increases were reviewed and approved by OTE. Once the speed authorization was signed, the appropriate speed limit signs were installed where necessary. The new speed limits were effective once the new speed limit signs were erected.

It is important to remember that raising a posted speed limit is not inherently making a road “less safe.” A properly selected speed limit can increase the safety of the roadway by creating uniform travel speeds for all vehicles and by setting realistic driver expectations of those trying to cross or enter the roadway.

¹ As Minnesota has gotten further into the study, it was noted that there were a few roadway control sections that were listed to be studied that were no longer two-lane 55mph roadways. In most of these instances, the roads were upgraded to 4-lane divided highways and no longer qualify for this study. In those cases, the control sections that are not two-lane 55 mph roads were removed from the schedule and the maps adjusted accordingly.

Other adjustments that were made to the schedule include: removing segments that were previously authorized at a speed limit that is lower than 55 mph and, moving segments into the proper district list because initially they were listed in the wrong district.

Study Methodology

To complete a speed study on a given corridor, MnDOT must collect several sets of data for each control section. While speed samples (actual speed measurements of vehicles) are a large part of the necessary data, there are other factors that must be considered during a speed study such as roadway geometrics and hazard assessments.

MnDOT district traffic engineers and the MnDOT Central Office Traffic Safety Unit met prior to the study kickoff to discuss and agree on the work requirements for the consultant contract for this study. The resulting worksheet is attached in Appendix D.

Items included on that worksheet are: access points, shoulder width, vertical grades, clear zone assessments, crash history, passing zones and speed samples. Following is Appendix A, which is a glossary that contains a discussion of the items under consideration on the worksheet.

Appendix A: Glossary

Access Points

An access point refers to public roads, a business driveway, a private driveway or a farm field access. During the planning process, it was determined that most rural highways have an average of seven to nine access points per mile. Fewer access points per mile means drivers are responding to a reduced number and variety of events.

Shoulder Width

The Highway Safety Manual was used as a basis for the shoulder width consideration. The HSM has a default value of 6-foot wide shoulders. A decrease to 5-foot wide shoulders represents a 4 percent increase in the number of crashes. A shoulder, both paved and unpaved, provides a recovery area for errant vehicles and space for disabled vehicles to park.

Vertical Grades

Grade is the rate of change of the vertical alignment. Grade affects vehicle speed and vehicle control, particularly for large trucks.

Clear Zone Assessment

A clear zone is an unobstructed, relatively flat area beyond the edge of the traveled way that allows drivers to stop safely and regain control of their vehicle that leaves the traveled way.

Crash Rate

Several different crash rates will be compared during this analysis: the total crash rate, the fatal and serious injury crash rate and the critical crash rate. A crash rate can be an effective tool to measure the relative safety at a particular location. The crash rate is a combination of crash frequency and vehicle exposure.

Total Crash Rate Equation:

$$\text{Total Crash Rate} = (\text{total crashes}) * 1,000,000 / (\text{Length} * \text{ADT} * \text{Years} * 365 \text{ Days/Year})$$

Due to the random nature of crashes, a statistical evaluation is used to determine which locations are below the average crash rate, performing near the average crash rate, those that are above the average crash rate and those that are statistically significant (i.e. critical) above the crash rate. Using a critical crash rate helps to ensure that locations being selected are actually having something significant happening, and are not just a result of the random nature of crashes. The Critical Crash Rate helps to filter out areas with low Average Daily Traffic or evaluated over a short time period.

$$R_c = R_a + K * (R_a/m)^{1/2} + .5/m$$

$$\text{Critical Crash Rate} = \text{System wide average crash rate} + (\text{Confidence Interval/vehicle miles traveled})^{1/2} + (.5/\text{vehicle miles traveled})$$

$$K = \text{Confidence Interval; 99.5\% } K=2.756, 95\% K= 1.645, 90\% K= 1.282$$

Passing Zones

A passing zone is an area where drivers are allowed to pass other vehicles traveling in the same direction when opposing traffic is not present.

85th Percentile

The 85th percentile speed is a major parameter used by traffic engineers. It is the speed at or below which 85 percent of all vehicles are observed to travel under free flowing conditions past a nominated point. A vehicle is considered to be in free flow conditions when it is not impacted by the speed of a preceding vehicle.

10 MPH Pace

Ten mile per hour pace is a 10 mile-per-hour increment in speeds that encompasses the highest portion of observed speeds.

A speed study considers all of these elements when conducting the analysis. The district traffic engineer considers this analyzed data and their engineering judgment to determine the appropriate speed limit for a roadway.

Tables listing the road segments studied by year and the resulting speed limit recommendations are found in Appendices E, F and G.

Appendix B: Total Miles for Study by MnDOT District

*Table 2: 55 MPH Trunk Highways – By Lane Mile and MnDOT District**

MnDOT District	Roadways in a Single District	Roadways in Multiple Districts	Total Lane Miles**

8	146	584	729

**Trunk highways that do not cross boundaries into another district are scheduled for study at the discretion of the district. The schedule for conducting speed studies on the roadways which cross multiple district boundaries is in Appendix C.*

***Totals may not add up exactly due to rounding*

Appendix C: Schedule of Speed Studies from 2014-2018

As Minnesota got further into the study, it was noted that there were a few roadway control sections that were listed in 2014 to be studied that were no longer two-lane 55 mph roadways. In most of these instances, the roads were upgraded to four-lane divided highways and no longer qualified for this study. In those cases, the control sections that were not two-lane 55 mph roads were removed from the schedule and the maps adjusted accordingly.

Other adjustments that were made to the schedule include: removing segments that were previously authorized at a speed limit which is lower than 55 mph and moving segments into the proper district list because initially they were listed in the wrong district.

*Table 3: Speed Study Schedule 2014-2018: Multi-District Roadways**

MnDOT District	Year 1: 2014	Year 2: 2015	Year 3: 2016	Year 4: 2017	Year 5: 2018	Total Miles / Multi-District Roadways

Appendix D: Speed Study Screening Evaluation List

Screening Considerations for Evaluating Rural Two-Lane Highways

Highway Number:

Date:

Control Section:

Evaluator:

Considerations
1. The number of access points (public roads, residential, commercial, industrial, etc.) is below an average of 10 access points per mile
2. Shoulder width (regardless of material type) is at 5 feet or greater
3. Vertical grades remain at or less than 3 percent (positive or negative) for the majority of the segment
4. A clear zone assessment was made of the corridor and determined to be satisfactory based on engineering judgment.
5. The total 5-year crash rate and/or the fatal and serious injury rate (with junction crashes) is below the statewide average for its ADT range
6. The total 5-year crash rate and/or the fatal and serious injury rate (with junction crashes) is below the critical crash rate based on statewide averages for its ADT range
7. Passing zones will meet the posted speed design standard
8. The 85 th percentile of free flow vehicles is at or above the proposed posted speed limit (per ITE recommendations)
9. The 10 mph pace has its upper boundary is at or above the proposed posted speed limit (per ITE recommendations)

Other Comments:

Statewide Crash Rates

Five Years of Crash Data	CR	FAR
Rural 2-lane : $ADT \in [0, 1500)$	0.64	4.01
Rural 2-lane : $ADT \in [1500, 5000)$	0.56	2.60
Rural 2-lane : $ADT \in [5000, 8000)$	0.62	2.32
Rural 2-lane : $ADT \in [8000, \infty)$	0.72	1.87

Symbol Explanation

\in represents a range or set that the ADT may fall into.

A square bracket [signifies that the number is included in the set and a rounded bracket or parenthesis (indicates that number is not included in that set.

So, for example:

$ADT \in [0, 1500)$ could be read as “having an ADT from 0 to 1499.”

Explanation of the Screening Considerations for Evaluating Rural Two- Lane Highways

1. **Access Points** – The number of access points per mile comes from the district and county roadway safety plans. During this planning process, it was found that most rural highways had an average of seven to nine access points per mile. The choice of 10 access points was chosen that most average roads would meet this consideration, but roads with significantly higher access densities should be evaluated for crash history. Posted speeds may be raised if engineering judgment indicates it is safe to do so.
2. **Shoulder Width** - The shoulder width consideration was based on the Highway Safety Manual. The HSM has a default value of 6 foot shoulders. A decrease to 5-foot shoulders represents only a 4 percent increase in the number of crashes.
3. **Vertical Grades** – HSM has an increased crash modification factor for grades in excess of 3 percent during a given segment.
4. **Clear Zone Assessment** - Every roadway being considered as a candidate to raise the speed should have a clear zone assessment completed. Roadways should have an acceptable amount of hazard free, forgiving roadside for the clear majority of the road. Hazards within the clear zone should be identified and based on risk should either be removed or documented as being an acceptable risk.
5. **Crash History** – Two types of crash rates will be examined: total crash rate and the fatal/serious injury crash rate. Roadways should be evaluated using the 5-year statewide crash rates for segments (with intersections included). Evaluations should document: if crash rates are below average for both rates, that there is not a speed related crash problem and that there are no other traffic safety issues.
6. **Crash History** – Two types of crash rates will be examined: total crash rate and the fatal/serious injury crash rate. Roadways should be evaluated using the 5-year statewide crash rates for segments (with intersections included). It should be documented if both crash rates are below the computed critical crash rate for both rates.
7. **Passing Zones** – Passing zones should be reviewed and understood to ensure that safe passing can still occur where signing is posted.
8. **85th percentile** – The Institute of Transportation Engineers uses this recommendation and process for determining how to set speed limits. MnDOT’s Traffic Engineering Manual also uses this process.
9. **10 mph pace** - The Institute of Transportation Engineers uses this recommendation and process for determining how to set speed limits. MnDOT’s Traffic Engineering Manual also uses this process.
